Abstract

This paper proposed a generalized estimator of population mean in the presence of correlated and uncorrelated measurement errors under simple random strategy. Some known estimators belong to this class of proposed estimator. Under the large sample approximation, the properties of the proposed estimator namely bias and mean squared error were obtained. Theoretical comparison was carried out on the members of the proposed class of estimators when measurement errors are correlated and when they are uncorrelated and the necessary conditions under which the proposed estimator at its optimum value is expected to be more efficient than the existing estimators of finite population mean were obtained. It was observed that correlated and uncorrelated measurement errors inflate the bias and mean squared error of the proposed estimator. The paper concluded that the proposed estimator is more efficient than usual unbiased estimator \bar{y} and some members of the class of proposed estimator.

Keywords: Measurement errors; generalized estimator; bias; mean squared error; correlation coefficient.

1 Introduction

Notwithstanding the mathematical development in sampling survey, the general assumption in sampling survey is that data used in estimating population parameters are free of observational errors or measurement errors at

__

^{}Corresponding author: Email: okafor_iyke@yahoo.com;*

data collection stage. In practice, this is not always the case as observed values in most case differ from the true value hence the data available for statistical analysis are subject to error. This may be due to the fact that all phases of sampling survey are possible sources of error. This can also be attributed to the bias on the part of the respondents or enumerators or both and due to natural variation in the subject, variation in the measurement process, or both (see Cochran [1], Biemer et al. [2]).

The difference between the individual observed values and their corresponding true values is termed measurement error. Measurement errors form a significant element of errors in any survey data and their presence may not be noticeable unless the responses are compared with some known standard values or the measurement processes are replicated a good number of times.

When measurement errors are present in both the study and auxiliary variables or present in either study variable or auxiliary variable, the influence drawn from the sample about the population parameter may be bias and inconsistent subject to the level of the measurement errors. Thus to a large extent, the efficiency of an estimator is a function of the magnitude of the measurement errors.

In sampling, measurement errors have been studied by Sukhatme and Sukhatme (1970) and Cochran [1], focusing on mathematical models to study the influence of measurement errors on estimators of population parameters. Shalabh [3] developed a methodology for studying the influence of measurement errors on estimators like the ratio estimator in sampling survey. Following Shalabh [3] methodology, Manish and Singh [4] proposed class of ratio estimator when measurement errors are present in the variables. This estimator is a linear combination of ratio estimator and sample mean per unit estimator. Erum and Javid [5] studied the effect of measurement errors on estimation of finite population mean for a sensitive variable using dual auxiliary information. The results which they obtained from theoretical and empirical analysis shows that their proposed estimator performs better than some existing estimators under study.

Qi et al. [6] studied the estimation of population mean in the presence of measurement errors and non-response error under stratified random sample and presented a comparison of the proposed estimator with some existing estimators which they found to be uniformly better than some existing estimators. Gajendra et al. [7] proposed ratio and regression type calibration estimators for the population mean under both correlated and uncorrelated measurement errors. The variances of the proposed calibrated estimators to the first order approximation were obtained and their efficiencies comparison with the usual unbiased estimator carried out. The result shows their proposed calibrated estimator to be uniformly better than the usual unbiased estimator. Using Monte Carlo simulation they studied the effect of measurement errors on the proposed calibrated estimators. They calculated the percentage contribution of measurement errors (PCME) and found that PCME of the proposed calibrated estimators increases with the increase in variability of the measurement errors present in both study and auxiliary variables. Decrease in PCME was recorded by them when measurement errors are positively correlated, the reverse is the case when they are negatively correlated.

The influence of measurement errors and randomized response technique on mean estimation under stratified double sampling was studied by Ronald et al. [8]. The numerical analysis carried out on the efficiency of the proposed estimator using simulated and real dataset revealed that the use of the Randomized Response Technique (RRT) in a survey contaminated with measurement errors increases the variances and mean squared errors of estimators of the finite population mean. Study has shown that the properties of ratio estimator is distorted by the presence of measurement error on the auxiliary variate. It is on this premise that the statistical properties of three common ratio estimators was studied by Gregoire and Salas [9] when measurement error is present in the auxiliary variable. Under the effect of systematic measurement error, the bias is irregular around zero and precision may be enhanced or vitiated subject to the extent of the error. When the measurement error is stochastic in nature, the bias of classical ratio-of-means estimator is much affected so also is the mean square error when compared with the other estimators which they considered. In summary, they concluded that ratioof-means estimator appears to be less affected by the measurement error in the auxiliary variants.

Neha and Gajendra [10] proposed a generalised class of estimators for mean when both study variable and auxiliary variable are contaminated with measurement errors under simple random sampling. To evaluate the performance of the proposed class of estimators, they carried out simulation and empirical analysis and their result shows that the proposed class of estimators is more efficient than the ratio and product estimators for any value of correlation coefficient. Azeem and Hanif [11] studied mean estimation when measurement errors and non-response exist simultaneously and presented theoretical and empirical analysis of the efficiency of the proposed estimator. Their findings show that the proposed estimator is more efficient than three other estimator they considered and also less bias than the two of the three estimators considered. Shalabh and Tsai (2017) have proposed ratio and product method of estimation in the presence of correlated measurement error.

In this paper, we propose a generalized class of estimators of the population mean of study variable under the influence of measurement errors. Some existing estimators are a member of this class of estimators. The effect of measurement error on the mean square error of the proposed class of estimators be explored. Many authors have studied the effects of measurement error on ratio, product and regression estimator. The main objective is to obtain simultaneously the properties of particular members of the proposed class of estimators under the influence of measurement errors. Also will carried theoretical comparison of the performance of the members of proposed class estimators when the measurement errors are correlated when the measurement errors are uncorrelated.

2 Notations

In obtaining the properties of the proposed estimator, we will assume large sample approximation. Let the population mean and variance of *X* and *Y* be defined as

$$
\bar{X} = \frac{1}{N} \sum_{i=1}^{N} X_i, \qquad \bar{Y} = \frac{1}{N} \sum_{i=1}^{N} Y_i, \qquad \sigma_X^2 = \frac{1}{N} \sum_{i=1}^{N} (X_i - \bar{X})^2, \qquad \sigma_Y^2 = \frac{1}{N} \sum_{i=1}^{N} (Y_i - \bar{Y})^2
$$

Further we define the coefficient of variation of X and Y as

$$
C_X = \frac{\sigma_X}{\overline{X}} \qquad \text{and} \qquad C_Y = \frac{\sigma_Y}{\overline{Y}}
$$

respectively. Also Covariance of Y and X, Correlation Coefficient between Y and X, and Correlation Coefficient between u and v are defined as

$$
\sigma_{XY} = \frac{1}{N} \sum_{i=1}^{N} (X_i - \bar{X}) (Y_i - \bar{Y}), \qquad \rho = \frac{\sigma_{XY}}{\sigma_X \sigma_Y} \qquad \text{and} \qquad \rho^* = \frac{\sigma_{uv}}{\sigma_v \sigma_u}
$$

respectively. Using delta notation, we define the following:

$$
\delta_0 = \frac{\bar{y}}{\bar{Y}} - 1 \implies \bar{y} = \bar{Y}(1 + \delta_o) \tag{1}
$$

$$
\delta_1 = \frac{\bar{x}}{\bar{X}} - 1 \implies \bar{x} = \bar{X}(1 + \delta_1) \tag{2}
$$

Such that,

$$
E(\delta_0) = E(\delta_1) = 0 \tag{3}
$$

$$
E(\delta_0^2) = \frac{\sigma_Y^2}{n\overline{Y}^2} \left(\frac{\sigma_Y^2 + \sigma_v^2}{\sigma_Y^2} \right) = \frac{C_Y^2}{n} \left(\frac{\sigma_Y^2 + \sigma_v^2}{\sigma_Y^2} \right) = \frac{C_Y^2}{n\theta_Y}
$$
(4)

$$
E(\delta_1^2) = \frac{\sigma_X^2}{n\bar{X}^2} \left(\frac{\sigma_X^2 + \sigma_v^2}{\sigma_X^2}\right) = \frac{C_X^2}{n} \left(\frac{\sigma_X^2 + \sigma_v^2}{\sigma_X^2}\right) = \frac{C_Y^2}{n\theta_Y}
$$
(5)

$$
E(\delta_0 \delta_1) = \frac{1}{n\bar{Y}\bar{X}} (\sigma_Y \sigma_X \rho + \sigma_u \sigma_v \rho^*)
$$
\n(6)

79

where,

$$
\theta_Y = \left(\frac{\sigma_Y^2}{\sigma_Y^2 + \sigma_v^2}\right)
$$

$$
\theta_X = \left(\frac{\sigma_X^2}{\sigma_X^2 + \sigma_v^2}\right)
$$

are reliability ratio of study variable and auxiliary variable respectively and are bounded between 0 and 1

3 Measurement Error Model Definition

For a population $U = (U_1, U_2, ..., U_N)$ of size N. Let y and x denote study and auxiliary variables taking values y_i and x_i respectively on the $i^{t\Box}$ unit of U_i , $(i = 1, 2, ..., N)$.

Assume SRSWOR of size n is drawn from population U. Let \bar{y} and \bar{x} be the sample means of y and x respectively. Thus, for a simple random sampling method, let (y_i, x_i) be observed values instead of the true values (y'_i, x'_i) on the two characteristics (y, x) respectively for the i^{t} unit $(i = 1, 2, ..., n)$ in a sample of size n. Then the measurement errors which is the difference between the study variable and auxiliary variable are respectively defined under correlated and uncorrelated measurement errors as:

i. When the Measurement Errors are correlated

$$
u_i = y_i - y'_i
$$

\n
$$
v_i = x_i - x'_i
$$

\n
$$
E(u) = E(v) = 0
$$

\n
$$
Var(u) = \sigma_u^2 \qquad Var(v) = \sigma_v^2
$$

\n
$$
Cov(u, v) = \rho^* \sigma_u \sigma_v
$$

\nii. When the Measurement Errors are uncorrelated
\n
$$
u_i = y_i - y'_i
$$

\n
$$
v_i = x_i - x'_i
$$

\n
$$
E(u) = E(v) = 0
$$

\n
$$
Var(u) = \sigma_u^2 \qquad Var(v) = \sigma_v^2
$$

\n
$$
Cov(u, v) = 0
$$

 \overline{a}

Expressing observed value as a function of true value and measurement error we have,

$$
y_i = y'_i + u_i \tag{7}
$$

$$
x_i = x'_i + v_i \tag{8}
$$

The measurement errors u and v are also assumed to be independent.

4 Adapted Estimators

In the presence of correlated measurement errors, the traditional sample mean per unit estimator for estimating population mean is given by:

$$
t_0 = \bar{y} \tag{9}
$$

The variance is given as

$$
V(t_0) = \frac{C_Y^2}{n} \left(\frac{\sigma_Y^2 + \sigma_v^2}{\sigma_Y^2} \right) \tag{10}
$$

Shalabh and Jia-Ren (2016) proposed ratio and product estimator in the presence of correlated measurement error as

$$
t_r = \bar{y}\frac{\bar{X}}{\bar{x}}\tag{11}
$$

$$
t_p = \bar{y}\frac{\bar{x}}{\bar{X}}
$$
 (12)

They obtained the mean square error of ratio and product estimators as

$$
MSE(t_r) = \frac{\bar{Y}^2}{n} \left(C_Y^2 + C_X^2 - 2C_Y C_X \rho + C_Y^2 \frac{\sigma_u^2}{\sigma_Y^2} + C_X^2 \frac{\sigma_v^2}{\sigma_X^2} - 2 \frac{\sigma_u \sigma_v \rho^*}{\bar{Y} \bar{X}} \right)
$$
(13)

$$
MSE(t_p) = \frac{\overline{Y}^2}{n} \left(C_Y^2 + C_X^2 + 2C_Y C_X \rho + C_Y^2 \frac{\sigma_u^2}{\sigma_Y^2} + C_X^2 \frac{\sigma_v^2}{\sigma_X^2} + 2 \frac{\sigma_u \sigma_v \rho^*}{\overline{Y} \overline{X}} \right)
$$
(14)

In the presence of uncorrelated measurement error, the mean square errors of t_r and t_p were given as

$$
MSE(t_r) = \frac{\bar{Y}^2}{n} \left(C_Y^2 + C_X^2 - 2C_Y C_X \rho + C_Y^2 \frac{\sigma_u^2}{\sigma_Y^2} + C_X^2 \frac{\sigma_v^2}{\sigma_X^2} \right)
$$
(13)

$$
MSE(t_p) = \frac{\bar{Y}^2}{n} \left(C_Y^2 + C_X^2 + 2C_Y C_X \rho + C_Y^2 \frac{\sigma_u^2}{\sigma_Y^2} + C_X^2 \frac{\sigma_v^2}{\sigma_X^2} \right)
$$
(14)

5 Proposed Estimator

Motivated by the work of Shalabh and Jia-Ren [12], we proposed the following generalized estimator of population mean in the presence of correlated and uncorrelated measurement errors.

$$
t_{pro} = \bar{y} \left[\frac{\alpha \bar{X} + \psi}{\beta(\alpha \bar{x} + \psi) + (1 - \beta)(\alpha \bar{X} + \psi)} \right]^{\kappa}
$$
(15)

Where $\alpha > 0$, ψ can either be a function of known population parameter of auxiliary variable x or a real number, κ is any real number chosen so as to minimize the mean squared error of t_{pro} and $\beta = 0$ or 1

6 Properties of Proposed Estimator

The properties of the proposed estimator up to first order approximation are obtained using notations defined in section 2 thus:

Expressing (15) in terms of δ_i (i = 0, 1) we have

$$
t_{pro} = \bar{Y}(1+\delta_0) \left[\frac{\alpha \bar{X} + \psi}{\beta(\alpha \bar{X}(1+\delta_1) + \psi) + (1-\beta)(\alpha \bar{X} + \psi)} \right]^{\kappa}
$$
(16)

After simplification, (16) can be written as

$$
t_{pro} = \bar{Y}(1+\delta_0)[1+\beta\lambda\delta_1]^{-\kappa} \tag{17}
$$

Where,

$$
\lambda = \frac{\alpha \bar{X}}{\alpha \bar{X} + \psi}
$$

Assuming that $|\delta_1| < 1$, the expression $(1 + \beta \lambda \delta_1)^{-\kappa}$ can be expanded to a convergent infinite series using binomial expansion. Hence,

$$
t_{pro} = \bar{Y}(1+\delta_0)\left(1 - \kappa\beta\lambda\delta_1 + \frac{\kappa(\kappa-1)}{2!}(\beta\lambda\delta_1)^2 - O(\delta_1)\right)
$$
(18)

Ignoring high order of δ_1 and simplifying (18) we have

$$
t_{pro} = \bar{Y} \left(1 + \delta_0 - \kappa \beta \lambda \delta_1 + \frac{\kappa(\kappa - 1)}{2} \beta^2 \lambda^2 \delta_1^2 - \beta \lambda \delta_0 \delta_1 \right) \tag{19}
$$

$$
t_{pro} - \bar{Y} = \bar{Y} \left(\delta_0 - \kappa \beta \lambda \delta_1 + \frac{\kappa(\kappa - 1)}{2} \beta^2 \lambda^2 \delta_1^2 - \beta \lambda \delta_0 \delta_1 \right)
$$
 (20)

Taking expectation of (20) and made necessary substitutions using $(3) - (6)$, we obtained the bias of the proposed estimator (t_{pro})

i. When the measurement errors are correlated as

$$
Bias^*(t_{pro}) = \frac{\overline{Y}}{2n} \bigg[\kappa(\kappa - 1)\beta^2 \lambda^2 \frac{C_X^2}{\theta_X} - 2\kappa \beta \lambda \left(C_Y C_X \rho - \frac{\sigma_u}{\overline{Y}} \frac{\sigma_v}{\overline{X}} \rho^* \right) \bigg] \tag{21}
$$

ii. When the measurement error is uncorrelated ($\rho^* = 0$), as

$$
Bias(t_{pro}) = \frac{\overline{Y}}{2n} \bigg[\kappa(\kappa - 1)\beta^2 \lambda^2 \frac{C_x^2}{\theta_x} - 2\kappa \beta \lambda C_Y C_X \rho \bigg] \tag{22}
$$

Squaring and taking expectation of (20) and made necessary substitutions using $(3) - (6)$, we obtained the mean square error of the proposed estimator (t_{pro})

i. When the measurement errors are correlated as

$$
MSE^*(t_{pro}) = \frac{\bar{Y}^2}{n} \left[\frac{C_Y^2}{\theta_Y} + \kappa^2 \beta^2 \lambda^2 \frac{C_X^2}{\theta_X} - 2\kappa \beta \lambda \left(C_Y C_X \rho + \frac{\sigma_u \sigma_v}{\bar{Y} \bar{X}} \rho^* \right) \right]
$$
(23)

The mean square error will be minimized when

Boniface et al.; AJPAS, 16(4): 77-92, 2022; Article no.AJPAS.85043

$$
\kappa = \frac{\theta_X \left(C_Y C_X \rho + \frac{\sigma_u}{\overline{Y}} \frac{\sigma_v}{\overline{X}} \rho^* \right)}{\beta \lambda C_X^2} \tag{24}
$$

Thus the minimum mean square error of t_{pro} is obtained as

$$
MSE_{min}^*(t_{pro}) = \frac{\overline{Y}^2}{n} \left[\frac{C_Y^2}{\theta_Y} - \frac{\theta_X \left(C_Y C_X \rho + \frac{\sigma_u}{\overline{Y}} \frac{\sigma_v}{\overline{X}} \rho^* \right)^2}{C_X^2} \right]
$$
(25)

ii. When the measurement error is uncorrelated $(\rho^* = 0)$, as

$$
MSE(t_{pro}) = \frac{\bar{Y}^2}{2n} \left[\frac{C_Y^2}{\theta_Y} + \kappa^2 \beta^2 \lambda^2 \frac{C_X^2}{\theta_X} - 2\kappa \beta \lambda C_Y C_X \rho \right]
$$
(26)

The mean square error will be minimized when

Table 1. Estimators and their mean square errors at different value of β , α , ψ and κ

$$
\kappa = \frac{\theta_X \mathcal{L}_Y \mathcal{L}_X \rho}{\beta \lambda \mathcal{C}_X^2} \tag{27}
$$

Thus the minimum mean square error of t_{pro} is obtained as

$$
MSE_{min}(t_{pro}) = \frac{\bar{Y}^2}{n} \left[\frac{C_Y^2}{\theta_Y} - \frac{\theta_X C_Y^2 C_X^2 \rho^2}{C_X^2} \right] = \frac{\bar{Y}^2}{n} \left[\frac{C_Y^2}{\theta_Y} - \theta_X C_Y^2 \rho^2 \right]
$$
(28)

Some particular members of the proposed estimator of population mean and their mean square error can be obtained by chosen suitable values of β , α , ψ and κ (see table below).

Where,

$$
\lambda_i = \frac{\alpha_i \bar{X}}{\alpha_i \bar{X} + \psi_i}, \qquad (i = 4, 5, \dots, 25)
$$

7 Theoretical Efficiency Comparison

The proposed estimator t_{pro} was compare with some particular members of the proposed estimators shown in Table 1. The results obtained are as follows

i. In the presence of correlated measurement error

1.
$$
MSE_{min}^*(t_{pro}) < V(t_{pro1}) \text{ if}
$$

$$
V(t_{proj}) - MSE_{min}^{*}(t_{proj}) = \frac{\theta_X}{C_X^2} \Big(\rho C_Y C_X + \frac{\sigma_u \sigma_v}{\overline{Y} \overline{X}} \rho^*\Big)^2 > 0
$$

2.
$$
MSE_{min}^*(t_{pro}) < MSE^*(t_{pro2}) \text{ if}
$$

$$
MSE^{*}(t_{proj}) - MSE^{*}_{min}(t_{proj}) = \left(C_X - \frac{\theta_X}{C_X} \left(\rho C_Y C_X + \frac{\sigma_u \sigma_v}{\overline{Y} \overline{X}} \rho^*\right)\right)^2 > 0
$$

3.
$$
MSE_{min}^*(t_{pro}) < MSE^*(t_{pro3}) \text{ if}
$$

$$
MSE^{*}(t_{pro3}) - MSE^{*}_{min}(t_{pro}) = \left(C_X + \frac{\theta_X}{C_X} \left(\rho C_Y C_X + \frac{\sigma_u \sigma_v}{\overline{Y} \overline{X}} \rho^*\right)\right)^2 > 0
$$

4.
$$
MSE_{min}^*(t_{pro}) < MSE^*(t_{pro4}) \text{ if}
$$

$$
MSE^{*}(t_{pro4}) - MSE^{*}_{min}(t_{pro}) = \left(\lambda_{4}C_{X} - \frac{\theta_{X}}{C_{X}}\left(\rho C_{Y}C_{X} + \frac{\sigma_{u}\sigma_{v}}{\overline{Y}\overline{X}}\rho^{*}\right)\right)^{2} > 0
$$

5.
$$
MSE_{min}^*(t_{pro}) < MSE^*(t_{pro5}) \text{ if}
$$

$$
MSE^{*}(t_{proj}) - MSE^{*}_{min}(t_{proj}) = \left(\lambda_{5}C_{X} + \frac{\theta_{X}}{C_{X}}\left(\rho C_{Y}C_{X} + \frac{\sigma_{u}\sigma_{v}}{\overline{Y}\overline{X}}\rho^{*}\right)\right)^{2} > 0
$$

6.
$$
MSE_{min}^*(t_{pro}) < MSE^*(t_{pro6}) \text{ if }
$$

$$
MSE^{*}(t_{\text{proof}}) - MSE^{*}_{\text{min}}(t_{\text{proof}}) = \left(\lambda_{6}C_{X} - \frac{\theta_{X}}{C_{X}}\left(\rho C_{Y}C_{X} + \frac{\sigma_{u}\sigma_{v}}{\overline{Y}\overline{X}}\rho^{*}\right)\right)^{2} > 0
$$

7.
$$
MSE_{min}^*(t_{pro}) < MSE^*(t_{pro7}) \text{ if}
$$
\n
$$
MSE^*(t_{pro7}) - MSE_{min}^*(t_{pro}) = \left(\lambda_7 C_X + \frac{\theta_X}{C_X} \left(\rho C_Y C_X + \frac{\sigma_u \sigma_v}{\overline{Y} \overline{X}} \rho^*\right)\right)^2 > 0
$$

8.
$$
MSE_{min}^*(t_{pro}) < MSE^*(t_{pro8}) \text{ if}
$$

$$
MSE^{*}(t_{pro8}) - MSE^{*}_{min}(t_{pro}) = \left(\lambda_8 C_X - \frac{\theta_X}{C_X} \left(\rho C_Y C_X + \frac{\sigma_u \sigma_v}{\overline{Y} \overline{X}} \rho^*\right)\right)^2 > 0
$$

9.
$$
MSE_{min}^*(t_{pro}) < MSE^*(t_{pro9}) \text{ if}
$$

$$
MSE^{*}(t_{\text{prog}}) - MSE^{*}_{\text{min}}(t_{\text{pro}}) = \left(\lambda_9 C_X + \frac{\theta_X}{C_X} \left(\rho C_Y C_X + \frac{\sigma_u \sigma_v}{\overline{Y} \overline{X}} \rho^*\right)\right)^2 > 0
$$

10.
$$
MSE_{min}^*(t_{pro}) < MSE^*(t_{pro10}) \text{ if}
$$

$$
MSE^{*}(t_{\text{pro10}}) - MSE^{*}_{\text{min}}(t_{\text{pro}}) = \left(\lambda_{10}C_{X} - \frac{\theta_{X}}{C_{X}}\left(\rho C_{Y}C_{X} + \frac{\sigma_{u}\sigma_{v}}{\overline{Y}\overline{X}}\rho^{*}\right)\right)^{2} > 0
$$

11.
$$
MSE_{min}^*(t_{pro}) < MSE^*(t_{pro11}) \text{ if}
$$

$$
MSE^{*}(t_{pro11}) - MSE^{*}_{min}(t_{pro}) = \left(\lambda_{11}C_{X} + \frac{\theta_{X}}{C_{X}}\left(\rho C_{Y}C_{X} + \frac{\sigma_{u}\sigma_{v}}{\overline{Y}\overline{X}}\rho^{*}\right)\right)^{2} > 0
$$

12.
$$
MSE_{min}^*(t_{pro}) < MSE^*(t_{pro12}) \text{ if}
$$

$$
MSE^{*}(t_{proj2}) - MSE^{*}_{min}(t_{proj}) = \left(\lambda_{12}C_{X} - \frac{\theta_{X}}{C_{X}}\left(\rho C_{Y}C_{X} + \frac{\sigma_{u}\sigma_{v}}{\overline{Y}\overline{X}}\rho^{*}\right)\right)^{2} > 0
$$

13.
$$
MSE_{min}^*(t_{pro}) < MSE^*(t_{pro13}) \text{ if}
$$

$$
MSE^{*}(t_{proj3}) - MSE^{*}_{min}(t_{proj}) = \left(\lambda_{13}C_{X} + \frac{\theta_{X}}{C_{X}}\left(\rho C_{Y}C_{X} + \frac{\sigma_{u}\sigma_{v}}{\overline{Y}\overline{X}}\rho^{*}\right)\right)^{2} > 0
$$

14.
$$
MSE_{min}^*(t_{pro}) < MSE^*(t_{pro14}) \text{ if}
$$

$$
MSE^{*}(t_{pro14}) - MSE^{*}_{min}(t_{pro}) = \left(\lambda_{14}C_{X} - \frac{\theta_{X}}{C_{X}}\left(\rho C_{Y}C_{X} + \frac{\sigma_{u}\sigma_{v}}{\overline{Y}\overline{X}}\rho^{*}\right)\right)^{2} > 0
$$

15.
$$
MSE_{min}^*(t_{pro}) < MSE^*(t_{pro15}) \text{ if}
$$

$$
MSE^{*}(t_{proj5}) - MSE^{*}_{min}(t_{pro}) = \left(\lambda_{15}C_{X} + \frac{\theta_{X}}{C_{X}}\left(\rho C_{Y}C_{X} + \frac{\sigma_{u}\sigma_{v}}{\overline{Y}\overline{X}}\rho^{*}\right)\right)^{2} > 0
$$

16.
$$
MSE_{min}^*(t_{pro}) < MSE^*(t_{pro16}) \text{ if}
$$

$$
MSE^{*}(t_{proto}) - MSE^{*}_{min}(t_{pro}) = \left(\lambda_{16}C_{X} - \frac{\theta_{X}}{C_{X}}\left(\rho C_{Y}C_{X} + \frac{\sigma_{u}\sigma_{v}}{\overline{Y}\overline{X}}\rho^{*}\right)\right)^{2} > 0
$$

8 Empirical Efficiency Comparison

An empirical efficiency comparison was carried out by comparing the mean square error of the proposed estimator with the mean square error of some estimators that belong to the proposed generalized estimator. The percentage relative efficiency of the proposed estimator and some estimators that belong to the proposed generalized estimator over sample mean per unit was obtained. The dataset for the empirical analysis was from Okafor [13] where,

 y_i = the observed land area of the village cultivated with maize x_i = the observed land area of the village avaliable for cultivation y_i' x_i^{\prime} and the following parameters were computed:

 $N = 20, \overline{X} = 829.1635, \overline{Y} = 530.0755, \sigma_Y^2 = 61824.97, \sigma_X^2$ $\sigma_u^2 = 9.5705, \sigma_v^2$ $\sigma_v = 3.0510$, $C_Y = 0.4691$, $C_X = 0.5262$, $\rho = 0.8139$, ρ^* $\beta_1(X) = 0.5735, \ \beta_2(X)$

The results were shown in Table 2.

Table 2. Mean square error and percentage relative efficiency

9 Discussion of Results

From the theoretical analysis, we observed that the bias of the proposed estimator t_{pro} is affected by the presence of measurement error on the auxiliary variable only. While the mean square error is affected by the presence of measurement errors both on the study and auxiliary variables. It is also our observation from both theoretical and empirical analysis that the proposed estimator t_{pro} at its optimum value yields the least mean square error when compared with the usual unbiased estimator \bar{y} and other members of the proposed class of estimator. Hence the proposed estimator recorded more gain in efficiency than the usual unbiased estimator \bar{y} and other members of the proposed class of estimator. The high positive correlation coefficient between study variable and auxiliary variable accounted for efficient performance of the ratio type estimators against product type estimators as can be seen in the figure below.

Fig. 1. Correlation Coefficient Between Study Variable (Y) and Auxiliary Variable (X)

The high positive correlation coefficient between study variable and auxiliary variable accounted for efficient performance of the ratio type estimators against product type estimators. There is no much difference on the effect of the presence of measurement errors on the mean square error of the proposed estimator when the measurement errors are correlated as when it is uncorrelated.

Unexpected result was observed for the estimator t_{pro22} which recorded a negative mean square error. The implication of this is that the combination of kurtosis and standard deviation of auxiliary variable for the purpose improving the performance of the ratio type estimator cannot yield an efficient estimator at least for the dataset used.

10 Conclusion

The stated inequalities in section 7 provide the necessary conditions under which the proposed estimator at its optimum value is expected to be more efficient than the existing estimators of finite population mean. The empirical analysis buttresses these conditions, therefore the proposed estimator at its optimum value is recommended for use in practice.
